ABSTRACT
Microstrip patch antenna becomes very popular day by day because of its ease of analysis and fabrication, low cost, light weight, easy to feed and their attractive radiation characteristics. Although patch antenna has numerous advantages, it has also some drawbacks such as restricted bandwidth, low gain and a potential decrease in radiation pattern. The aim of the thesis is to design and fabricate a line feed rectangular Microstrip Patch Antenna and study the effect of antenna dimensions Length (L), Width (W) and substrate parameters relative Dielectric constant, substrate thickness (t) on the Radiation parameters of Bandwidth and Beam-width.

KEYWORDS: Rectangular microstrip antennas, dielectric substrate, resonant microstrip, radiation patterns, GEMS Software.

I. INTRODUCTION
The Microstrip Patch Antenna is a single-layer design which consists generally of four parts: patch, ground plane, substrate, and the feeding part [1]. The physical size of a microstrip antenna is small, but the electrical size measured in wavelength is not so small [2]. The most commonly employed microstrip antenna is a rectangular patch. The rectangular patch antenna is approximately a one-half wavelength long section of rectangular microstrip transmission line. When air is the antenna substrate, the length of the rectangular microstrip antenna is approximately one-half of a free-space wavelength. As the antenna is loaded with a dielectric as its substrate, the length of the antenna decreases as the relative dielectric constant of the substrate increases. The resonant length of the antenna is slightly shorter because of the extended electric "fringing fields" which increase the electrical length of the antenna slightly. An early model of the microstrip antenna is a section of microstrip transmission line with equivalent loads on either end to represent the radiation loss [3].

II. DESIGN PROCESS
This method of feeding is very widely used because it is very simple to design and analyze and very easy to manufacture. Figure-1 shows a patch with microstrip line feed from the side of the patch. The position of the feed point (y_0) of the patch in has been discussed in details in the section of Impedance Matching. It is widely used in both one patch antenna and multi-patches (array) antennas.

Figure-1: Microstrip patch antenna with feed from side
**Figure-2:** Top view of Microstrip Patch Antenna

**Step 1:** Calculation of width (W)
Width of the patch,
\[ W = \frac{c}{2f_0 \sqrt{\varepsilon_r + \frac{1}{2}}} \]

\[ f_0 = 3 \text{ GHz}, \varepsilon_r = 4.4, \quad c = 3.00 \times 10^8 \text{ m/s} \]
We get,
\[ W = 0.0304\text{mm} = 30.4\text{mm} \]

**Step 2:** Calculation of Effective dielectric constant (\( \varepsilon_{eff} \))

\[
\varepsilon_{eff} = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2} \left[ 1 + 12 \frac{h}{W} \right]^{1/2}
\]

\[ \varepsilon_r = 4.4, h = 1.3, W = 30.4\text{mm} \]
We get,
\[ \varepsilon_{eff} = 4.0822 \]

**Step 3:** Calculation of the Effective length (\( L_{eff} \))
The effective length is:
\[
L_{eff} = \frac{c}{2f_0 \sqrt{\varepsilon_{eff}}}
\]

\[ f_0 = 3 \text{GHz}, \varepsilon_r = 4.4, \quad c = 3.00\times10^8 \text{ m/s} \]

We get,
\[ L_{eff} = 0.0247 = 24.7\text{mm} \]

**Step 4:** Calculation of the length extension (\( \Delta L \))
The length extension is:
\[
\Delta L = 0.412h \left( \frac{\varepsilon_{eff} + 0.3}{W} + 0.264 \right) - \left( \frac{\varepsilon_{eff} - 0.264}{W} \right) \frac{W}{h} + 0.8
\]

\[ \varepsilon_{eff} = 4.0822, h = 1.3, W = 30.4\text{mm} \]
We get,
\[ \Delta L = 6.0016\text{mm} - 0.04 = 6.0016\text{mm} \]

**Step 5:** Calculation of actual length of patch (L)
The actual length is obtained by:
\[ L = L_{eff} - 2\Delta L \]
\[ \Delta L = 6.0016\text{mm}, L_{eff} = 24.7\text{mm} \]
We get,
\[ L = 0.0235 = 23.5\text{mm} \]

**Step 6:** Calculation of Total characteristic impedance of the Microstrip transmission line
Total characteristic impedance of the Microstrip transmission line
$$Z_L = \sqrt{Z_1 + Z_2}$$
$$Z_1 = \text{probe impedance} = 50\Omega$$
$$Z_2 = \text{Total input impedance of the rectangular patch antenna} = 317.9778$$
We get,
$$Z_L = 126.0908$$

**Step 7:** Calculation of Length of the Microstrip transmission line
Length of the Microstrip transmission line
$$TL = \frac{\lambda}{4} = \frac{\lambda_0}{4\sqrt{\varepsilon_r}}$$
$$\lambda_0 = \frac{c}{f_0} = 3\text{GHz}, \varepsilon_r = 4.4, \quad c = 3.00 \times 10^8 \text{ m/s}$$
We get,
$$TL = 0.0119 = 11.9\text{mm}$$

**Step 8:** Calculation of Directive Gain of the antenna
Directive Gain of the antenna
$$G = e_r D$$
$$= 3.5066$$
Where $$D = 2.2 \times 10^{17}$$ and $$e_r = 1.6 \times 10^{-17}$$

### III. SIMULATION AND RESULT

The GEMS software used to model and simulate the Microstrip patch antenna and it also used for calculating and plotting Return loss, VSWR, current distributions, radiation patterns etc. GEMS (general electromagnetic solver) are a Full 3-D Parallel EM Simulation Software and System.

#### 3.1 Return loss and Antenna Bandwidth:
To design a rectangular microstrip patch antenna we decide the substrate material and the thickness of it. Design an antenna for the IEEE 802.11b/g, in the band of 3GHz.

![Figure-3: Microstrip patch antenna designed using GEMS for 3 GHz.](image)

**Return Loss:**

As show in figure-4 the simulation indicates a response at 2.937GHz with return loss = -8.314dB. A negative value of return loss shows that this antenna had not many losses while transmitting the signals.
Antenna Bandwidth:

From the same figure the antenna bandwidth was calculated by using this formula:

\[
\text{Bandwidth} = \frac{f_2 - f_1}{\sqrt{f_1 f_2}} \times 100\%
\]

The value of \(f_1\) and \(f_2\) were taken at \(-6\)dB or 6% from the transmitted power.

\[
\text{Bandwidth} = \frac{2.981G - 2.903G}{\sqrt{2.981G \times 2.903G}} \times 100\% = 2.6515\%
\]

IV. CONCLUSION

As we observe the table-1 which displays all the parameters and the results for the design. There are different dimensions, dielectric constant, and frequencies. Having gone through the results it happened to be a bit difficult to decide the optimized design of the antenna, as there are different aspects that are involved in the design of the antenna. We can say that there are many aspects that affect the performance of the antenna. Dimensions, selection of the substrate, feed technique and also the operating frequency can take their position in effecting the performance.

V. FUTURE WORK

It is very important to take the feed technique the impedance and the substrate is main parameters into consideration. The proper position to terminate the Feed line also affects the performance of the antenna. In future other different type of feed techniques can be used to calculate the overall performance of the antenna without missing the optimized parameters in the action.
